

Job lifecycle: (1) log in; (2) `POST /jobs` via DNS to a healthy job service; (3) multipart upload straight to presigned URLs in the home cloud; (4) on `submit`: SHA-256 verified, acceptance receipt in *both* clouds, then `ACCEPTED` and `202`; (5) runners pull a lease for their pool; (6) read the published input, write a create-only attempt prefix, publish via a fenced conditional commit; (7) report verified in both clouds, then `COMPLETED` and download via a presigned URL. **Teal:** cross-cloud traffic. VM cap: 2 system + 14 CPU + 4 GPU = 20; managed services (DB, Fargate/Cloud Run, K8s masters) are outside it.
